## The Debate: Surface or Volume?

- Do transfer or knockout experiments measure surface properties (ANC, reduced width), or volume properties (norm of overlap function)?
- Theory: only ‘asymptotic properties’ are observable: invariant under off-shell (interior) unitary transformations.
- Reply: We have relied on local potentials for interior forms
- Conclusion: We must:
- pay attention to invariance if we derive effective potentials (which may be local or non-local)
- separate the contributions from interior and exterior
- see if/how these contributions depend on higher-order couplings.

## Transfers to Resonances?

Not clear what do we measure when we compare
(a) experimental magnitude to theory magnitude?
(b) experimental width to theory width?

Need a new general theory for resonant transfers!

- Preferably one easy to calculate!
- At present, to get convergence at large radii: we use bins, or complex contour, or damping
- Should calculate actual shape of resonance peak
- Include wide / overlapping / multichannel resonances
- Ideally should fit using R-matrix resonance parameters

## New work <br> A.M. Mukhamedzhanov, PRC 84, 044616 (2011)

- Look at dependence of transfer rate on $r_{n A}$
$=$ radius of neutron wave function $\phi_{n}\left(r_{n A}\right)$ being probed
- Remember that $\phi_{n}\left(r_{n A}\right)$ for $r_{n A}>r_{s}$ (surface radius) depends on the reduced width: $\gamma^{2}$ or the ANC: C

$$
\begin{aligned}
& \quad \gamma^{2}=\frac{\hbar^{2}}{2 \mu a} \phi_{n}(a)^{2} \quad \phi_{n}\left(r_{n A}\right) \rightarrow_{r_{n A} \rightarrow \infty} C W\left(k r_{n A}\right) \\
& \text { (when } \left.\int_{0}^{a} \phi_{n}(r)^{2} d r=1\right)
\end{aligned}
$$

- Look at how post and prior transfers depend on maximum value of $r_{n A}$ (cut wfn to zero outside).
- Later, try to express as much of the transfer as possible in terms of the $\gamma^{2}$.
- This will help calculation of transfers to resonances
- Needed e.g. for Trojan Horse methods, and many expts.

## Post and Prior DWBA Transfer Couplings

- Consider a deuteron $\mathrm{d}=\mathrm{n}+\mathrm{p}$ incident on target A , and the $A(d, p) B$ reaction, with $B=A+n$.
- Binding potentials $\mathrm{V}_{\mathrm{np}}$ for $\phi_{\mathrm{d}}(\mathrm{r})$, $\mathrm{V}_{\mathrm{nA}}$ for $\phi_{\mathrm{n}}\left(\mathrm{r}_{\mathrm{nA}}\right)$
- Entrance \& exit optical potentials $U_{d A}(R), U_{p B}(R)$
- Also need 'core-core' potential $U_{p A}$

Look at DWBA as first approximation:

- $\mathrm{T}_{\text {post }}=\left\langle\mathrm{f}_{\mathrm{p}}^{(-)} \phi_{\mathrm{n}}\right| \mathrm{V}_{\mathrm{np}}+\mathrm{U}_{\mathrm{pA}}-\mathrm{U}_{\mathrm{pB}}(\mathrm{R})\left|\phi_{\mathrm{d}} \mathrm{f}_{\mathrm{d}}{ }^{(+)}\right\rangle$(has ZR limit)
- As long-ranged in $r_{n A}$ as $\phi_{n}$, as $V_{n p}$ acts at all distances from target
- $\mathrm{T}_{\text {prior }}=\left\langle\mathrm{f}_{\mathrm{p}}(-) \phi_{\mathrm{n}}\right| \mathrm{V}_{\mathrm{nA}}+\mathrm{U}_{\mathrm{pA}}-\mathrm{U}_{\mathrm{dA}}(\mathrm{R})\left|\phi_{\mathrm{d}} \mathrm{f}_{\mathrm{d}}^{(+)}\right\rangle$
- Short-ranged in $r_{n A}$ than $\phi_{n}$, as $V_{n A}, U_{p A}, U_{d A}$ all cut off away from target

## Effects of limiting max $r_{n A}$

Bound state

Resonance bin at 1 MeV

Peak cross sections, calculated in the post and prior formalisms, are shown as a function of the cutoff radius, (beyond which contributions from the neutron wave function are set to zero)
The cross sections are normalized relative to the peak cross sections obtained in the full calculation.
See that Post contributions are from large neutron radii. Convergence to resonances is slow (especially for post form) Very small post contributions from the interior

## 'Surface Amplitude’ component

- Define $T_{\text {post }}(a, b) \& T_{\text {prior }}(a, b)$ with $a<r_{n A}<b$ limits Mukhamedzhanov (PRC 84, 044616, 2011) showed recently:

$$
\begin{aligned}
& \mathrm{T}=\mathrm{T}_{\text {post }}(0, a)+\mathrm{T}_{\text {surf }}(a)+\mathrm{T}_{\text {prior }}(a, \infty) \\
& \left.\quad \text { where } \mathrm{T}_{\text {surf }}(a)=\left\langle\mathrm{f}_{\mathrm{p}}^{(-)} \phi_{\mathrm{n}}\right|[\overleftarrow{T}-\vec{T}]\left|\phi_{\mathrm{d}} \mathrm{f}_{\mathrm{d}}^{(+)>}\right\rangle_{(n)}\right)
\end{aligned}
$$

- Evaluate:

$$
\begin{aligned}
& \int_{r \leqslant R} \operatorname{dr} f(\mathbf{r})[\overleftarrow{T}-\vec{T}] g(\mathbf{r}) \\
& \quad=-\frac{1}{2 \mu} \oint_{r=R} \mathrm{~d} \mathbf{S}\left[g(\mathbf{r}) \nabla_{\mathrm{r}} f(\mathbf{r})-f(\mathbf{r}) \nabla_{\mathrm{r}} g(\mathbf{r})\right] \\
& \quad=-\frac{1}{2 \mu} R^{2} \int \mathrm{~d} \Omega_{\mathrm{r}}\left[g(\mathbf{r}) \frac{\partial f(\mathbf{r})}{\partial r}-f(\mathbf{r}) \frac{\partial g(\mathbf{r})}{\partial r}\right]_{r=R}
\end{aligned}
$$

## $T=T_{\text {post }}(0, a)+T_{\text {surf }}(a)+T_{\text {prior }}(a, \infty)$

Prove post-prior equivalence in DWBA:

- If $a=0$, then, since $T_{\text {surf }}(0)=0$, find $T=T_{\text {prior }}(0, \infty)$
- If $a=\infty$, then, since $T_{\text {surf }}(\infty)=0$, find $T=T_{\text {post }}(0, \infty)$

Dependence on reduced width $\gamma^{2}$ of neutron wf:

- If $a$ is outside radius of the potential, then $T_{\text {surf }}(a)+T_{\text {prior }}(a, \infty)$ depend on wfn only by $\gamma^{2}$
- Only dependence on interior is by (small) $\mathrm{T}_{\text {post }}(0, a)$

## Size of the Surface Term

Bound state

Resonance

$$
T_{\text {surf }}(a)=T_{\text {prior }}(0, a)-T_{\text {post }}(0, a)
$$

Now we see the surface term peaked at the surface (as expected).
But it does not produce all the cross section peak, or all the integral

## CDCC Breakup exterior calculations

- The potentials in the prior matrix element

$$
V_{n}+U_{p A}-U_{d}(R)
$$

are very similar to the

$$
U_{n A}+U_{p A}-U_{d}(R)
$$

used in CDCC breakup calculations. Difference is that $\mathrm{V}_{\mathrm{n}}=$ binding potl and $\mathrm{U}_{\mathrm{nA}}=$ optical potl.

- If we can ignore this difference, and calculate $\Psi C D C C$, then the 'exterior prior' term disappears:

$$
\mathrm{T}=\mathrm{T}^{C D C C} \text { post }(0, a)+\mathrm{TCDCC}_{\text {surf }}(a)
$$

- For now:
regard the 'exterior prior' as indicator of breakup.

## Interior / Surface / Breakup

Breakup outside radius on x-axis

Interior wfn contribution inside $x$-axis radius

Plotting sqrt(cross-section) - to estimate amplitudes

## Predictions for future CDCC-surface calculations

```
\(\mathrm{T}^{\mathrm{CDCC}}\) surf \((a)=\mathrm{T}-\mathrm{T}^{\mathrm{CDCC}}\) post \((0, a)\)
    \(\approx T_{\text {post }}(a, \infty)\)
                            -- use this to estimate:
```

Black curve ratio of post cross sections $\sigma_{\text {post }}(a, \infty) / \sigma=\left|T_{\text {post }}(a, \infty) / T\right|^{2}$
Try to choose radius around $7.5-8 \mathrm{fm}$ outside potential, where the CDCC-surface contribution is complete

Ratio of cross section peaks
Larger interior contribution for this bound-state transfer

## Conclusions

- See development of a model that separates

1. Interior contributions from shape of wave function
2. Breakup contributions from exterior tails
3. Dominant 'surface contribution' from exterior tails.

- 'Surface Approximation': if neglect other terms
- Good prospects for
- a new model of transfer reactions to resonances, that
- uses small-radius calculations (convergent!),
- to map R-matrix parameters onto resonance shapes.
- We are now developing the CDCC approach
- In future: fit neutron R-matrix parameters from expt.

## I. INTRODUCTION

AREDUCED width for the emission of a single nucleon in a transition between two specific nuclear states can be regarded as a product of two factors. Of these factors, the first is a measure of the probability that, in the initial nuclear state, all but one of the nucleons will find themselves in an arrangement corresponding to the final state; the second factor measures the probability that, when this happens, the two components will actually separate. The factorization is formally expressed by

$$
\begin{equation*}
\theta^{2}=S \theta_{0}{ }^{2} . \tag{I.1}
\end{equation*}
$$

It is clear that the "spectroscopic factor" S, which depends only on the wave functions of the nuclear states involved, provides a useful basis for comparison between experiment and the predictions of current nuclear models.

## Define 'spectroscopic factor' S

 = ratio of observed reduced width to that of single-particle stateMaybe something for us to learn here?

## TORUS <br> Theory of Reactions of Unstable Isotopes

DOE Topical Collaboration
Ian Thompson, LLNL Jutta Escher, LLNL

Filomena Nunes, MSU Neelam Upadhyay (PD)

Akram Mukhamedzhanov (TAMU)
V. Eremenko (PD)

Charlotte Elster (OU)
Goran Arbanas (ORNL)

Aim: develop new methods that will advance nuclear reaction theory for unstable isotopes by using three-body techniques to improve direct-reaction calculations
